The Swedish Work Environment Authority's Statute Book

The Swedish Work Environment Authority's provisions and general recommendations on occupational exposure limit values;

AFS 2011:18

Published on 16th
December 2011.

Adopted 29 November 2011.

The following Provisions¹ are issued by the Swedish Work Environment Authority pursuant to Section 18 of the Work Environment Ordinance (1977:1166) and the following general recommendations are adopted.

Aim and areas of application

1 § The aim of these provisions is to prevent ill health resulting from exposure to the agents listed herein.

These provisions apply to all activities where air contaminants occur or are formed.

¹ cf. the following directives:

- Council Directive 94/42/EC of 7 April 1998 on the protection of the health and safety of workers from the risks related to chemical agents at work (fourteenth individual Directive within the meaning of Article 16 (1) of directive 89/391/EEC) (EGT L 131, 5.5.1998, p. 11, Celex 31998L0024).
- Directive 2004/37/EEC of the European Parliament and of the Council of 29 April 2004 on the protection of workers from the risks related to exposure to carcinogens or mutagens at work (Sixth individual Directive within the meaning of Article 16(1) of Council Directive 89/391/EEC) (EUT L 158, 30.4.2004, p. 50, Celex 32004L0037).
- Directive 2009/148/EC of the European Parliament and of the Council of 30 November 2009 on the protection of workers from the risks related to exposure to asbestos at work (EUT L 330, 16.12.2009, p. 28, Celex 32009L0148).
- Commission Directive 91/322/EEC of 29 May 1991 on establishing indicative limit values by implementing Council Directive 80/1107/EEG on the protection of workers from the risks related to exposure to chemical, physical and biological agents at work. (EGT L 177, 5.7.1991, p. 24, Celex 31991L0322).
- Commission Directive 2000/39/EC of 8 June 2000 establishing a first list of indicative occupational exposure limit values in implementation of Council Directive 98/24/EC on the protection of the health and safety of workers from the risks related to chemical agents at work. (EGT L 142, 16.6.2000, p. 47, Celex 32000L0039).
- Commission Directive 2006/15/EC of 7 February 2006 establishing a second list of indicative occupational exposure limit values in implementation of Council Directive 98/24/EC and amending Directives 91/322/EEC and 2000/39/EC. (EUT L 38, 9.2.2006, p. 36, Celex 32006L0015).
- Commission Directive 2009/161/EU of 17 December 2009 establishing a third list of indicative occupational exposure limit values in implementation of Council Directive 98/24/EC and amending Commission Directive 2000/39/EC (EUT L 338, 19.12.2009, p. 87, Celex 32009L0161).

AFS 2011:18

General recommendations: Air contaminants can contain elements of chemical, microbiological and other organic air contaminants. Organic air contaminants can be, for example, flour dust or epithelial skin from animals.

When workers are exposed to several types of air contaminants, the following provisions of the Swedish Work Environment Authority apply at one and the same time:

- occupational exposure limit values
- chemical work environment risks,
- microbiological work environment risks – infection, toxigenic effect, hypersensitivity.

Definitions

2 § Within the provisions, the following terms and definitions apply.

Air contaminant	A substance or a mixture of substances present in air which, if over a certain level, can cause ill health.
Occupational exposure	The highest acceptable average content level of an air contaminant in air which is to be inhaled, calculated as a time weighted average. A hygienic limit value is either a level limit value or a ceiling value.
Level limit value	An occupational exposure limit value for exposure during a working day, normally 8 hours.
Ceiling limit value	An occupational exposure limit value for exposure during a reference period of 15 minutes. For ammonium, monoisocyanates and diisocyanates a 5 minute reference period applies.
Short term value	A recommended highest value for exposure calculated as time weighted average over a reference period of 15 minutes. Short term values are the recommended values. They serve as a guideline in protection work and are used in the assessment of exposure conditions.

When assessing and measuring the content of air contaminants

3 § The content level of air contaminants in inhaled air shall be acceptable according to the limit values described in Appendix 1.

To ensure that content levels are acceptable, they shall be tested through an assessment of exposure, in accordance with section 9 of the provisions regarding chemical hazards in the working environment and, if necessary, through measurement of exposure, in accordance with sections 4-7 of these provisions.

General recommendations: It may be necessary to carry out measurements when, for example, new equipment is first used or when changes in work activities could result in air contamination.

When there is a choice of more than one limit value for a substance or air contaminant, the lower value shall apply, as exposure must be acceptable with respect to all limit values.

How the content of air contaminants shall be measured

4 § The person measuring air contaminants shall have undergone education which provides both theoretical and practical knowledge of

- how measurements are planned and carried out,
- how measurement data shall be treated,
- how results should be interpreted,
- how these can be shown in a measurement report according to Appendix 2.

General recommendations: It is important that the person carrying out the measurements has the requisite knowledge of current measurement methods, how measurements should be carried out, measurement uncertainty, measurement error sources and is familiar with the instruments to be used. It is also important that this person has good insight into the prevalent conditions in the workplace concerned.

How measurements can be carried out and used for the assessment of exposure is described in the standard Workplace atmospheres – Guidance for the assessment of exposure by inhalation to chemical agents for comparison with limit values and measurement strategy (SS-EN 689).

AFS 2011:18

5 § Measurements shall be planned in co-operation between employers and concerned employees, in addition to safety representatives, if such should exist.

The analytic methods and the equipment to be used should be suitable for the agents which are to be measured. Particular attention should be paid to the specific properties of the measuring equipment and the duration of exposure.

General recommendations: When measuring, samples are collected which will later be analyzed in a laboratory. The measurement equipment being used may mean that pumps are required and these must be calibrated before use. Other equipment may require the use of direct reading instruments, which saves all the measurement data which is later to be evaluated.

6 § Measurements shall be carried out in a breathing zone on as many people as possible, so that exposure can be assessed for all involved. Measurements shall refer to normal operating conditions. They shall also, where required, illustrate exposure under other conditions.

General recommendations: The purpose of the measurement is to acquire as accurate a picture of the exposure as possible. There is often a connection between exposure levels and the way in which various people carry out their work. This means that measurement of exposure, especially on the first occasion, may need to involve a number of those who are subject to exposure in the workplace. However, at workplaces where several persons are judged to have a similar level of exposure, measurement of every fifth person is sufficient.

The measurement positioning measurement or test equipment as close as possible to the nose and mouth, i.e. the distance should not exceed the 0.3 m breathing zone.

In cases where there is still a high content level in the air, despite measures taken in accordance with the provisions on chemical hazards in the working environment, measurements can be taken from inside a protective mask or visor. Low exposure levels inside the mask may still mean that measures are required to reduce exposure in the surrounding area.

For the possibility to calculate the exposure when breathing masks are used and when measurements are performed outside of these, the level of protection provided by the mask must be known; this should be evident from the mask's directions for use. Another factor which can affect the function of the protective device is leakage, where the mask does not fit tightly enough to the face due to hair growth, or where the breathing mask

fits poorly or is the wrong size, or where the protective equipment has been poorly maintained.

7 § The measurement shall be carried out over a period long enough to ensure reliability and so that results can be compared with a level limit value. The portion of the working hours included in the measurement shall be representative of the exposure. If exposure only occurs during a certain part of the day, then it is sufficient to carry out measurements at that time.

If the work is carried out in shifts, measurements shall be taken during the various shifts, according to the manner in which the work differs from shift to shift.

The measurement shall cover the time period to which the ceiling value refers and be carried out at those times when exposure can be assumed to be at its highest, so that the results of the measurement can be compared with a ceiling value.

When there is reason to suspect a high level of transient air contaminants, and there is no ceiling value, exposure can be compared with the short term value. A sampling such as this should be carried out for a period of 15 minutes. When someone is exposed to agents with synergistic effects and similar mechanisms of action, the combined effect of the agents shall be assessed.

General recommendations: The average content level, i.e. the time weighted average of an air contaminant, is acceptable if the limit value is not exceeded. Isolated transgressions can be tolerated if the average value for several measurements lies under the limit value. The objective should be that the quality of air to be inhaled is such that the average content level of the air contaminants does not exceed the limit value, even for short periods during part of a working day. A working day normally comprises eight hours and, as a rule, measurement should be carried out for at least 75 % of the working hours. It is not acceptable that a part-time employee be exposed to higher levels of air contaminants due to their shorter total exposure time. In the event of longer working periods, 12 hours for example, a standard referencing method may be employed. The method involves reducing the limit value proportionately through the multiplication of a factor of $8/X$, where X is the length of the working day, in hours. In the 12 hour example, the limit value would be multiplied by a factor of $8/12$.

Exposure equivalent to a 15 minute ceiling value should not occur for more than 15 minutes per hour. Exposure equivalent to a 5 minute ceiling value should not occur more than once every 20 minutes.

AFS 2011:18

Time weighted average: The measured average concentration of the air contamination shall be calculated as a time weighted average. With full-time sampling, this value is produced directly from measurement. With part-time sampling, the time weighted average value C_m is calculated using the following formula:

$$C_m = \frac{C_1 x t_1 + C_2 x t_2 + C_3 x t_3 + \dots + C_n x t_n}{t_1 + t_2 + t_3 + \dots + t_n}$$

where C_1, C_2, C_3 etc. is the measured content for each part-time sample, and t_1, t_2, t_3 etc. is the sampling time for each part-time sample. An example of the calculation of the average content level of a substance can be found in Appendix 3.

In order to achieve sufficient certainty in the measurement results, 75% of working hours should be measured, as a rule. If exposure varies a great deal during the course of a normal working day, it may be necessary to carry out measurements throughout the whole working day.

Hygienic effect: For substances with synergistic effects and similar effect mechanisms, the combined effect of the substances shall be assessed. This is done through the calculation of the hygienic effect which is equivalent to the sum of the quotients between the measured content for each substance and their hygienic limit value. Exposure is usually considered to be acceptable if the hygienic effect is 1, at the highest.

The combined, additive, hygienic effect can be summarized in the following formula:

$$HE = \frac{C_1}{G_1} + \frac{C_2}{G_2} + \frac{C_3}{G_3} + \dots + \frac{C_n}{G_n}$$

where C_1, C_2, C_3 etc. are measured content levels for the substances 1, 2, 3 etc. and G_1, G_2, G_3 etc. are the limit values for these substances, expressed as the same unit. An example of the calculation of hygienic effect can be found in Appendix 3. The narcotic, intoxicating or anaesthetic effects which organic solvents have on the central nervous system are one example of an instance when the effects of different substances should be combined.

For solvents whose hygienic limit value is established with consideration for effects other than those which affect the central nervous system, e.g., benzene, a separate assessment shall be made. For benzene, the limit value is set based on its carcinogenic effect and, in terms of the limit value

level, benzene contributes only very slightly to the general effects of the solvent.

How the results shall be documented

8 § The measurement results shall be documented in a measurement report. The documentation shall contain all necessary information so that the exposure to air contaminants can be assessed. The information found in Appendix 2 shall always be accounted for in the measurement report.

General recommendations: A particular protocol is followed when measurements are carried out. When the measurement results are complete, a measurement report is produced. Sufficient information is required, in order for the exposure to air contaminants to be assessed. It is therefore important that the measurement report fully describes the conditions which prevailed at the time the measurements were carried out, i.e. the quantities, the number of manufactured units per day, etc. and that the report states any deviations from the norm. Please refer to Appendix 2 of these provisions for further details. The measurement report can provide information regarding the efficiency of any measures taken. Furthermore, the report can form the basis for later assessments, should further exposure measurements need to be carried out. The measurement report can also be an important source of information for other surveys of exposure levels.

Section 3 of the Work Environment Ordinance states that measurement reports resulting from professional hygienic measurements shall be available for at least 5 years. If activities are transferred, then the measurement reports shall be assigned to the new operator.

Measures to take when limit values are exceeded

9 § If a measurement of air contaminants shows that the hygienic limit values, according to these provisions, have been exceeded, actions shall be taken to lower exposure and reduce the risks.

Recommendations on the measures to be considered can be found in section 16 of the Swedish Work Environment Authority's provisions on chemical hazards in the working environment.

AFS 2011:18

Entry into force and transitional stipulations

1. This statute enter into force on 1 July 2012 and at the same time the Swedish Work Environment Authority's provisions (AFS 2005:17) on hygienic limit values and measures against air contaminants are repealed.

2. As far as the limit value for bisphenol A in Appendix 1 is concerned, this statute comes into force on 18 December 2011.

3. Authorizations granted according to the repealed provisions, shall apply in accordance with the Swedish Work Environment Authority's provisions (AFS 2011:19) on chemical hazards in the working environment.

MIKAEL SJÖBERG

Claes Trägårdh

Anna Middelman

Appendix 1

List of limit values

Explanations of the terms used in the list

Limit values exist for various types of air contaminants and also for groups of agents.

For agents with a dust limit value, the list states whether this applies to inhalable dust, total dust or respirable dust. The definitions for the various sorts of dust are described in note 2 to the list of limit values. The limit values for the various entities are given according to the table below.

Type of air contaminant	Unit
Gases, vapours	mg/m ³ ppm (ml/m ³ , cm ³ /m ³)
Dust, smoke, haze, aerosol	mg/m ³
Enzymes	glycin units/m ³
Fibres	fibres/cm ³
Radon	Bq/m ³

For recalculation between ppm and mg/m³, the following formula has been used. This applies at 20 °C and 101,3 kPa (760 mm Hg). The values have been rounded off.

$$Conc.(mg / m^3) = \frac{Molarweight(g / mole)}{24,1(l / mole)} \times Conc.(ppm)$$

24.1 = molar volume at 20 °C and 101.3 kPa.

New substances or substances with retested limit values in relation to the Swedish Work Environment Authority's provisions on hygienic limit values and measures against air contaminants (AFS 2005:17) are marked with a #.

CAS no. is the agent's identification number according to Chemical Abstract Service. A list of the CAS numbers of the agents in the list of limit values can be found in Appendix 4. The list also contains agents which are forbidden or for which authorization is required (A and B agents, respec-

AFS 2011:18

tively), please refer to the provisions on chemical hazards in the working environment.

* For group limit values', only one CAS number is given. For copper and inorganic compounds, the CAS number for copper is given. In these cases, the CAS number is marked with a *.

Year The year when the substance was introduced into the list, or when the limit value for a certain substance was last retested, is stated in the table.

In the column marked **remarks** it is stated whether the substance belongs to one of the categories below with the following symbols:

B = Exposure for certain chemical substances approaching existing professional hygienic limit values and simultaneous exposure to noise levels approaching the action value of 80 dB can cause damage to hearing.

C = The substance is carcinogenic.
There is a cancer risk even with an exposure other than inhalation. For certain carcinogenic substances which do not have limit values, prohibition may apply or authorization may be required, in accordance with the provisions on chemical hazards in the working environment.

H = The substance can easily be absorbed through the skin.
The prescribed limit value is deemed to provide sufficient protection only on the condition that the skin is protected against exposure to the substance in question.

M = Medical supervision may be required for handling of this substance.
Please refer to the provisions on occupational medical supervision. For certain substances, medical control is required only when the substance is used as a thermosetting plastic component. Please refer to the provisions on thermosetting plastics.

R = The substance may impair fertility.
This refers to substances which are considered to cause damaging effects to reproductive capacity or to the development of offspring. Please refer also to the provisions on chemical hazards in the working environment and on pregnant and breastfeeding employees.

S = The substance is sensitizing.
Sensitizing substances can lead to allergies or other hypersensitivity. Hypersensitivity problems mainly affect the skin or respiratory organs. Hypersensitivity means that persons react upon contact with substances which do not normally cause problems. Allergies are a

subgroup of hypersensitivity; they are caused by reactions within the body's immune system. Particularly low limit values have been set for substances with more pronounced respiratory passage-sensitizing properties.

Some substances with strong sensitizing properties may only be handled following authorization from the Swedish Work Environment Authority; please refer to the provisions on chemical hazards in the working environment. These substances have no limit values.

Notes concerning the list of limit values

- 1) The substance may not be handled. Certain exceptions exist however. For further information, please see sections 45–46 in the provisions on chemical hazards in the working environment, regarding the prohibitions and authorizations applicable to substances belonging to group A, please see Appendix 1.
- 2) **Inhalable** dust refers to the dust fraction defined in the Swedish standard SS-EN 481, Work Atmospheres – Size fraction definition for measurement of airborne particles, Edition 1, 1993, point 2.3 and which has a sampling characteristic in accordance with point 5.1.

Respirable dust refers to that dust fraction which is defined in the Swedish standard SS-EN 481, Work Atmospheres – Size fraction definition for measurement of airborne particles, Edition 1, 1993, point 2.11 and which has a sampling characteristic in accordance with point 5.3.

Total dust refers to particles (aerosols) which fasten to a filter in the proof stick as described in The Method Series, Sampling of total dust and respirable dust, Method no. 1010, the National Board of Occupational Safety and Health, now known as the Swedish Work Environment Authority. The filter diameter is normally 37 mm, but it can also be 25 mm. Despite its name, this method does not sample the total quantity of airborne particles.

Please also refer to the Comments regarding note 2 on the list of limit values on page 59.

- 3) Handling of this substance requires authorization from the Swedish Work Environment Authority. For further information please see sections 47–48 in the provisions on chemical hazards in the working environment and, regarding the prohibitions and authorizations applicable to substances belonging to group B, please see Appendix 1.
- 4) The ceiling value refers to a 5 minute period.
- 5) The table's specific limit values for nitrogen dioxide and carbon monoxide are intended to take into consideration the combined effect of those substances occurring in exhaust fumes, including carcinogenic substances. These substances are therefore used as indicator substances. Exposure shall be acceptable with respect to both values. It is likely that the size of the carbon monoxide value is based upon exposure to exhaust fumes from petrol and gas-driven engines, whilst the nitrogen dioxide value represents the equivalent for diesel engines. On the other hand, the hygienic effect between carbon monoxide and nitrogen dioxide should not be taken into consideration.
- 6) Gasoline, diesel oil, jet fuel, domestic fuel/heating oil and other petroleum-based fuels have no set limit values because they are composite blends of a large number of substances whose content levels are often not known in detail. Furthermore, they vary depending on the fuel type. What is stated here are approximated values which can be used in preventative safety work and in assessments made of a work site. The values represent the highest acceptable total content level of hydrocarbons in the air. They are used in the same way as the values in the list of limit values.

AFS 2011:18

Product	Maximum accept total content level of hydrocarbons in the air, mg/m ³ (time weighted average for a working day)
Aviation gasoline	350
Engine gasoline	250
Alkylate gasoline ¹	900
Jet fuel ²	250
Diesel Mk 1 ³	350
Heating oil	250

- 1) Special gasoline for engine-driven work equipment (Swedish standard SS 155461) e.g., chainsaws.
- 2) Also known as Jet A-1, aviation kerosene, etc.
- 3) Diesel (Mk 2 and Mk 3) with higher aromatic hydrocarbon content (max 20 and 25 %) also exists but it has a limited market.

For measurements of hydrocarbons, instruments or laboratory methods which provide the total content of the substances can be used. The instrument shall be calibrated against the fuel in question or, for example, pure octane.

- 7) The limit value refers to petrol containing less than 0.2 % benzene.
- 8) Industrial petroleum (special boiling point naphtha) is usually specified by stating specific boiling point intervals. Those types which are common in Sweden usually primarily contain either hexanes (c. 25–50 % n-hexane, boiling point interval c. 60–80 °C), heptanes (boiling point interval c. 80–110 °C) or octanes (boiling point interval c. 100–140 °C). Compare n-hexane, other hexanes, heptanes and octanes.
- 9) The limit value refers to petrol containing less than 5 % n-hexane.
- 10) p-Benzoquinone, quinone, can be transformed via a reduction process into hydroquinone. Hydroquinone can easily be transformed back into p-benzoquinone through oxidation by air. See also hydroquinone.
- 11) Benzo(a)pyrene can occur, amongst other polycyclic aromatic hydrocarbons (PAH), in smoke, dust or mist from i.e. tar and asphalt and in certain oils and combustible products.
- 12) The same limit values expressed in mg/m³ shall also be applied for those phthalates for which no limit value have been defined.
- 13) There are biological limit values for lead and cadmium; please see the provisions on medical controls in working life.
- 14) The same limit values expressed in ppm shall be applied for those lactates for which no limit values have been defined.
- 15) For dust or mist from substances which have specific limit values, these values should be applied.

- 16) Refers to dust from fully cured or nearly fully cured epoxy resin, acrylates, polyurethane and ester plastics, bakelite or similar. Also included here is dust from uncured powder material of an epoxy-type, etc.
- 17) A limit value of 0.5 mg/m³ should be applied for the assessment of dust from impregnated wood.
- 18) The limit value refers to aliphatic hydrocarbons in vapour form, i.e. up to 12 carbon atoms. Upon exposure to hydrocarbons with more than 12 carbon atoms, which occur in the form of aerosols, particles or drops of liquid, the limit value of organic dust and mist should be applied: 5 mg/m³. The limit value does not apply to dearomatized white spirit (<2% aromatic by weight) which has its own limit value; see note 36.
- 19) For substances which do not have an occupational exposure limit value in Sweden, it is recommended that the EU limit value be used as a guideline until the Swedish value has been introduced.

The following substances have no Swedish limit value but have guidance limit values in accordance with the European Commission's directives 91/322/EEC, 2000/39/EC, 2006/15/EC and 2009/161/EU.

Substances	CAS-no	Level Limit Value		Short term Value		Com
		ppm	mg/m ³	ppm	mg/m ³	
1,1-Dichloroethane	75-34-3	100	412	-	-	H
Bisphenol A	80-05-7	-	10	-	-	-
Diethyleneglycole monomethylether (2-(2-etoxyetoxy) etanol))	111-77-3	10	50	-	-	H
1,2,4-Trichloro- benzene	120-82-1	2	15	-	-	H
Diphosphorus pentasulfide	1314-80-3	-	1	-	-	-
Sulfotep	3689-24-5	-	0,1	-	-	H
Picricacid	88-89-1	-	0,1	-	-	-
Pyrethrum	8003-34-7	-	1	-	-	-
Sodium azide	26628-22-8	-	0,1	-	0,3	H

- 20) The same limit values expressed in ppm shall be applied to diisocyanates for which no limit values have been defined. The same applies to diisocyanates in dust or mist

AFS 2011:18

form and aerosols, including prepolymerized isocyanates and adducts. The equivalent values expressed in mg/m^3 are different for the various substances.

- 21) In vapour form, the substance can be absorbed through the skin to a significant degree.
- 22) The level limit value 1 ppm applies for the sum of contents comprising dimethyl disulfide, dimethyl sulfide and methyl mercaptan.
- 23) Absorption of the substance in liquid form through the skin is so extensive that it can cause life-threatening injuries.
- 24) The limit value applies for subtilisin and similar proteolytic enzymes. A glycine unit corresponds to an activity which, from standard substrate under standard conditions, releases as many amino groups as are found in 1 mg of glycine.
- 25) The limit value applies to the combined concentration of vapour and aerosol.
- 26) With respect to the risk for injury to reproductive function and to the major absorption via the skin of liquids and vapours, it is particularly important that contact with the skin is avoided. In the event of simultaneous exposure to several solvents, the hygienic effect of reproduction-function-damaging ethylene glycol ethers and other solvents is calculated separately; please refer to the provisions chemical hazards in the working environment. The contribution by ethylene glycol ethers to other solvent effects than reproduction can be disregarded. Some of the ethylene glycol ethers require handling permission from the Swedish Work Environment Authority. For further information, please refer to the provisions on chemical hazards in the working environment.
- 27) The fibres to be taken into account for comparison with the limit value are respirable fibres which have a length-width relationship greater than 3:1, a diameter less than $3\text{ }\mu\text{m}$ and a length greater than $5\text{ }\mu\text{m}$. The limit value assumes that fibre calculation is carried out with a phase contrast microscope. For exposure to dust containing fibres, the limit value for inorganic dust shall also apply.
- 28) Minerals which can occur as natural crystalline fibres include attapulgite, halloysite, sepiolite and wollastonite.
- 29) The most common refractory ceramic fibres are aluminium silicate fibres (CAS no: 142844-00-6).
- 30) For exposure to a mixture of fluorides and hydrogen fluorides, the level limit value for fluorides shall be applied.
- 31) The same limit values expressed in mg/m^3 shall be applied to phthalates for which no limit values have been defined. The following phthalates have a damaging effect on reproductive function:

	CAS no
Di(2-methoxyethyl)phthalate	117-82-8
Di(2-ethylhexyl)phthalate	117-81-7
Dibutylphthalate	84-74-2
Benzylbutylphthalate	85-68-7
Diisobutylphthalate	84-69-5
- 32) The following isocyanates are included in the list of limit values:

Diisocyanates:	Monoisocyanates:
Hexamethylen diisocyanate, HDI	Diisopropylphenyl isocyanate
Isophorone diisocyanate, IPDI	Phenyl isocyanate
4,4-Methylene diphenyl diisocyanate, MDI	Isocyanic acid, ICA
Naphthalene diisocyanate, NDI	Methyl isocyanate, MIC
Toluen diisocyanate, TDI	

33) Methylisocyanate and isocyanic acid can be formed from hot work involving polyurethane and other carbon-based contaminants containing nitrogen. The requirement for medical control is only necessary when the substance is formed through the thermal degradation of plastics as described in the provisions regarding thermosetting plastics.

34) Turpentine from Scandinavian coniferous trees is skin-sensitizing. The sensitizing effect of specific turpentines has however not been scientifically confirmed, with the exception of 3-Carene.

35) Carbon dioxide is often used as an indicator substance in workplaces where air contaminants principally occur as a result of the people working there. Please see the specific rules regarding ventilation in the provisions on workplace design.

36) This refers to white spirits, i.e. petroleum spirits whose component parts can primarily be found in the area C₇ to C₁₂ and which have less than 0.1 per cent by weight of benzene. Compare with note 40 on white spirits. The stated approximate value in ppm for petroleum spirits with 2-25 per cent aromatic hydrocarbons is calculated based on petroleum spirits with 22 per cent by weight of aromatic hydrocarbons. The stated approximate value in ppm for white spirits with < 2 per cent by weight aromatic hydrocarbons (dearomatized white spirit (<2% aromatic)) is calculated on petroleum spirits free of aromatic hydrocarbons with 50 % cyclic aliphates.

37) Methylene chloride and trichloroethylene are also regulated by the Swedish Chemicals Agency's legislation and by REACH legislation.

38) Certain oils can produce polycyclic aromatic hydrocarbons upon heating, which can be carcinogenic. Furthermore, mineral oils can themselves contain such substances.

39) For haze from water-based cutting fluid or similar, which can also include substances other than oil, the value for the total content of the water-free part is applied. For substances with lower individual limit values, these are applied.

40) White spirits consist of a mixture of petroleum hydrocarbons, which usually have a boiling point interval of 135 - 200 °C. Terms such as aromatic naphtha and aliphatic naphtha can be used for white spirits with almost 100% aromatic hydrocarbons or almost 100% aliphatic hydrocarbons. Petroleum spirit with 17-22 % aromatic hydrocarbons is a type of white spirit. Specific limit values apply for petroleum spirit (see note 36). The limit values for other types of white spirits are calculated based on the composition and limit values of their components.

41) For underground work, the limit value for has been given for total exposure over the course of a year and may not exceed 2.1×10^6 Bq h/m³ for work underground (annual working time = 1,600 hours). This value is equivalent to an exposure of approximately 1,300 Bq/m³. Underground work includes rock and mining work, building work or similar which is carried out underground.
For other underground work, such as work in prepared and furnished rock shelters, facilities built into the rock, premises and similar, the radon content may not exceed 0.72×10^6 Bq h/m³, (annual working time = 1,800 hours). This value is equivalent to an exposure of approximately 400 Bq/ m³. Determination of radon concentration

AFS 2011:18

should be carried out in accordance with the Swedish Radiation Safety Authority's method describing procedures for the measurement of radon in the workplace.

- 42) For other work, other than underground work, the limit value for radon gas has been given for total exposure over the course of a year and may not exceed 0.36×10^6 Bq h/m³ for work above ground (annual working time = 1,800 hours. This value is equivalent to an exposure of approximately 200 Bq/m³. Determination of radon concentration should be carried out in accordance with the Swedish Radiation Safety Authority's method describing procedures for the measurement of radon in the workplace.
- 43) This comprises stearates such as salts and esters, amongst others.

	CAS number
Aluminium monostearate	7047-84-9
Aluminium distearate	300-92-5
Aluminium tristearate	637-12-7
Ammonium stearate	1002-89-7
Butyl stearate	123-95-5
Diethylene glycol monostearate	106-11-6
Ethylene glycol monostearate	111-60-4
Glycerol monostearate	31566-31-1
Calcium stearate	1592-23-0
Potassium stearate	593-29-3
Lithium stearate	4485-12-5
Magnesium stearate	557-04-0
Sodium stearate	822-16-2
Zinc stearate	557-05-1

- 44) The limit value does not apply to those metal stearates which contain toxic metals, i.e. lead. In this case, the limit value for lead shall be used.
- 45) Trichloroethylene contains certain stabilizing substances. Trichloroethylene for use in particularly demanding technical purposes can, as an additive, contain low levels of specially constructed stabilizing substances which can contain, for example, epichlorohydrin.
- 46) The same limit value expressed in mg/m³ shall also be applied for other polyalkylbenzenes.

Comments regarding note 2 on the list of limit values

Dust definitions

Health-related size fractions for airborne particles and aerosols are defined in the standard Workplace Atmospheres – Size fraction definitions for measurement of airborne particles (SS-EN 481). They are made up of inhalable, thoracic and respirable particle fractions. The inhalable fraction is the quantity of particles, out of the total number of particles in the air, which can be inhaled through the nose and mouth. The thoracic fraction is the part of the inhalable particles which passes through the larynx. The respirable fraction is the inhalable particles which progress furthest down into the airways, to the alveoli in the lungs. This is illustrated in diagram 1. The diagram shows that proof sticks for inhalable dust capture 50 % of particles with an aerodynamic diameter of 100 μm , proof sticks for thoracic dust capture 50 % of the 10 μm particles and proof sticks for respirable dust capture 50 % of the 4 μm particles.

Smoke particles from welding, for example, are, as a rule, primarily of a magnitude of $< 1 \mu\text{m}$, which means that, according to the standard, these consist to a large extent of respirable particles. This implies that all smoke particles can be regarded as being respirable. Proof sticks with pre-separators are therefore not required for sampling where only smoke is concerned. Metallic smoke is generally formed through condensation and possible oxidation of metallic vapour. Welders often also carry out grinding or slagging, which is why even the airborne dust in a welder's breathing

AFS 2011:18

zone can consist of a high percentage of non-respirable dust. In Sweden, *testing cassettes* with a diameter of 25mm or 37 mm are used for the sampling of what is known as total dust. The term total dust should not be confused with the total quantity of airborne particles in the air, of which total dust is only one part.

The dust convention for *inhalable dust* deviates so much from the older term of total dust that the content of air contaminants, and therefore also the limit values, cannot be directly compared with each other. Investigations carried out by the Swedish Work Environment Authority, among others, indicate that the quantity of inhalable dust can be two to three times greater than the quantity of total dust sampled in the same working environment. The difference also depends on the type of dust involved.

The Swedish Work Environment Authority, in their establishment of limit values, also use the term total dust as the definition of inhalable dust according to the standard SS-EN 481. Up to now, there is no stated limit value of thoracic dust.

Appendix 2

Information to be included in a measurement report

- The company's name, address and the location of the workplace.
- The business operation and the number of employees concerned with the air contamination for which the measurement is being carried out.
- The date of the measurement.
- Which substance(s) have been measured.
- The purpose of the measurement.
- Who has carried out the measurement.
- Production and ventilation information.
- Climate information, for measurements taken outside.
- A sketch or photographs of the workplace.
- Job rotation, if relevant to exposure.
- Personal protective equipment used, if any, and when.
- The average time spent on respective work tasks, over the course of a day, week and year, if this can be assessed.
- The total working time per day, start and stop, shift working, if applicable and details of longer breaks and rest periods.
- The occurrence of heavy, physically demanding work.
- The names of the people and the work tasks that the measuring concerns and at what times the measurements were carried out.
- Test sites and test times for each sample taken.
- Method of measurement and equipment used.
- Analytical results, analytical method and the analytic laboratory engaged.
- Compilation of measurement results with time weighted day averages and work tasks plus the applicable hygienic limit values.
- An assessment, with comments, comparisons and details of any earlier measurements, other investigations, etc., recommended actions and a conclusion.

Appendix 3

Example of the calculation of time weighted averages and hygienic effect

Four samples of solvent A have been taken with portable measurement equipment during one day, according to the following:

Sample 1	07.50 – 10.00	130 min	67 ppm
Sample 2	10.00 – 12.00	120 min	54 ppm
Sample 3	12.35 – 14.20	105 min	35 ppm
Sample 4	14.20 – 16.05	105 min	48 ppm

The time weighted average value, according to the formula in the commentary to section 7 will then be:

$$C_m = \frac{67 \times 130 + 54 \times 120 + 35 \times 105 + 48 \times 105}{130 + 120 + 105 + 105} = \frac{8710 + 6480 + 3675 + 5040}{460} = \frac{23905}{460} = 52$$

$C_m = 52$ ppm. The level limit value is 70 ppm. Exposure to solvent A therefore lies under the level limit value.

During the same time periods as above and in the same sampling, solvent B was also analyzed and the results for the contents of the samples were 12, 22, 7 and 16 ppm respectively.

$$C_m = \frac{12 \times 130 + 22 \times 120 + 7 \times 105 + 16 \times 105}{460} = \frac{1560 + 2640 + 735 + 1680}{460} = \frac{6615}{460} = 14$$

$C_m = 14$ ppm. The level limit value is 20 ppm.

The combined, additive, hygienic effect will be, according to the commentary in section 7:

$$HE = \frac{52}{70} + \frac{14}{20} = 0,7 + 0,7 = 1,4$$

When the hygienic effect is over 1 for simultaneous exposure to solvent A and solvent B, this means that the limit value has been exceeded.

*Appendix 4***CAS number index**

This index contains CAS numbers for the substances listed in the list of limit values (pages 16–52) and the substances found in the notes (pages 53–58). Substances which are forbidden (A) or require permission (B) according to the Swedish Work Environment Authority's provisions on chemical work environment risks are also included.

CAS no	Substance	Not
50-00-0	Formaldehyde	
50-32-8	Benzo(a)pyrene	
51-79-6	Carbamic acid ethylester	B
53-96-3	2-Acetamidofluorene	A
54-11-5	Nicotine	
55-63-0	Nitroglycerine

10108-64-2	Cadmium dichloride	
10588-01-9	Sodium dichromate	See Chromium (VI)

AFS 2011:18

CAS no	Substance	Not
11070-44-3	Methyl tetrahydro phtalic anhydride	
12001-28-4	Crocidolite	
12001-29-5	Crysotile	
12035-72-2	Trinickel disulfide	
12172-73-5	Amosite	
12510-42-8	Erionite	A
13149-00-3	cis-Hexahydro phtalic anhydride	B
13463-39-3	Nickel carbonyl	
13463-67-7	Titanium dioxide	
13466-78-9	3-Carene (cf. terpenes)	
13494-80-9	Tellurium	
13530-65-9	Zink chromate	See Chromium(VI)
13838-16-9	Enflurane	
13952-84-6	sec.-Butyl amine	
14166-21-3	trans-Hexahydro phtalic anhydride	B
14464-46-1	Cristobalite	
14807-96-6	Talc	
14808-60-7	Quartz	
15468-32-3	Tridymite	
15646-96-5	2,4,4-Trimethyl hexa methylene diisocyanate	See diisocyanates
15950-66-0	2,3,4-Trichlorophenol	
16111-27-6	S-[2-(Dimethylamino)ethyl]-pseudo thiourea dihydrochloride	B

CAS no	Substance	Not
	ride) (PBA 1	
16938-22-0	2,2,4-Trimethylhexamethylene diisocyanate	See diisocyanates
19234-20-9	Ethylene glycol monoisopropyl ether acetate	
19438-60-9	Hexahydro-4-methyl phthalic anhydride	B
25013-15-4	Vinyltoluene	
25154-54-5	Dinitrobenzene	
25167-82-2	Trichlorophenol	
25167-83-3	Tetrachlorophenol	
25321-14-6	Dinitrotoluene	
25550-51-0	Methylhexahydro phthalic anhydride	B
25551-13-7	Trimethylbenzene	
26471-62-5	Toluene diisocyanate	See diisocyanates
26590-20-5	1,2,3,6-tetrahydromethyl phthalic anhydride	B
26628-22-8	Sodium azide	
26675-46-7	Isoflurane	
26761-40-0	Diisodecyl phthalate	
28178-42-9	2,6-Diisopropylphenyl isocyanate	
28523-86-6	Sevoflurane	
28679-16-5	Trimethylhexamethylene diisocyanate	See diisocyanates
31566-31-1	Glycerol monostearate	
34090-76-1	Tetrahydro-4-methyl	

AFS 2011:18

CAS no	Substance	Not
phtalic anhydride	B	
34590-94-8	Dipropyleneglycol mono-methyl ether	
42498-58-8	2,3,5,6-Tetrahydro-2- methyl phtalic anhydride	B
48122-14-1	1-Methylhexahydroptalic anhydride	B
57041-67-5	Desflurane	
57110-29-9	Hexahydro-3-methylphtalic anhydride	B
